1 Homomorphisms and quotient groups

1.1 Generators and group presentations

We can imagine the subgroup generated by x as x being thrown in a box with itself and shook around. So what if we throw in more elements to be shook together?

Definition: Subsets as group generators

The subgroup generated by a subset S of G, $\langle S \rangle$, is the set of finite productive between elements of S and their inverses.

- S = [a, b], then $\langle S \rangle$ is stuff like $abababa, \, a^5b^3ab^2, \, a^{-1}bab^{-100}$
- If $\langle S \rangle = G$, then S is a **set of generators** for G

Example: \mathbb{Z}

 $\langle 1 \rangle = \mathbb{Z},$ because each integer can be written as a bunch of 1's or a bunch of -1's
